ABSTRACT

Background: Ligamentum flavum cysts have been rarely described in the literature and are one of the rare causes of neural compression and canal stenosis. Very few cases of their association with neurologic deficits are reported to date, and association with acute onset weakness is even rarer.

Clinical Presentation: We report our experience with 3 cases of ligamentum flavum cyst that presented with acute onset weakness and also present a comprehensive literature review on lumbar ligamentum flavum cysts reported to date. All 3 patients had symptoms of severe neurogenic claudication and presented to us with acute onset of motor weakness in lower limbs. Ligamentum flavum cyst was located in the midline in 2 cases and laterally in 1 case. We performed excision of the cyst and decompression with fusion in 2 cases and decompression alone in 1 case. All 3 cases had significant improvement in their neurologic status postoperatively. Histopathological examination confirmed ligamentum flavum cyst in all 3 cases. We performed a PUBMED and EMBASE database search using the MeSH (Medical Subject Headings) terms “ligamentum flavum” and “cysts” for articles published to April 2019. We could identify 7 studies describing 20 cases of lumbar ligamentum flavum cysts with motor weakness in the literature. Only 1 case had been described with an acute onset of weakness.

Conclusions: Ligamentum flavum cysts should remain in the differential diagnosis of a patient who has symptoms of lumbar canal stenosis and presents with acute onset of neurological deficits. Such patients have a good improvement with surgery.

Lumbar Spine

Keywords: lumbar spine, ligamentum flavum cyst, acute onset neurologic deficit, cyst excision and confirmed on histopathology, literature review and case series

BACKGROUND

The most commonly reported cystic lesions in the spine are synovial cysts (lined by a true synovial lining) or ganglion cysts.^{1,2} Ligamentum flavum cysts were first reported by Moiel et al³ in 1967. Ligamentum flavum cysts are unique lesions without a synovial lining (cf synovial cysts) and are associated with a pseudocystic degeneration of the ligamentum flavum.⁴ They are a rare cause of canal stenosis and compression of neural structures. The origin of ligamentum flavum cysts was proposed to be secondary to microtrauma due to hypermobility at the spinal segment and associated degenerative changes.^{2,5} They are found mostly in the most mobile and degenerative segments of the spine, with almost more than half of ligamentum flavum cysts found in the lumbar spine at the L4–L5 level and the remainder at L5–S1 and L3–L4.⁶ Most often, they are diagnosed during surgery, but if looked at

closely, they can be diagnosed preoperatively by magnetic resonance imaging (MRI).⁷ The symptoms produced by ligamentum flavum cysts depend on their location, size, and rate of growth.⁶ Only a few cases of their association with neurologic deficits have been documented in the literature to date, and acute onset of weakness is even rarer. Various treatment modalities, including conservative methods such as analgesics, braces, physiotherapy, steroid injections, and even repeated aspiration of cysts, have been attempted for symptomatic ligamentum flavum cysts with less favorable results.⁶ Surgical resection of the cyst along with the affected ligamentum flavum removal is advised when they cause neurological symptoms or intractable pain.^{8,9} We present our experience with 3 cases of ligamentum flavum cysts that developed an acute onset of neurologic deficit.

Figure 1. Case 1. (a, b) Sagittal T1- and T2-weighted magnetic resonance images of the patient showing a lesion hypointense on T1 and hyperintense on T2 within the posterior spinal canal at the L4–L5 level compressing the thecal sac (marked with blue arrow). (c, d) Axial T1- and T2-weighted MRI image at the L4–L5 level of the patient showing a lesion with hypointense signal (similar to cerebrospinal fluid signal) on T1 imaging and hyperintense signal on T2 imaging in the midline and slightly to the left (marked with blue arrow). (e, f) Anteroposterior and lateral x-rays of the lumbosacral spine of the patient showing degenerative changes at the L4–L5 and L5–S1 levels. Grade 1 spondylolisthesis at L5–S1 can be appreciated on the lateral view.

CLINICAL PRESENTATION

Case 1

A 55-year-old female presented to us with symptoms of neurogenic claudication for the past 1 month and acute onset of weakness in both legs for the past 10 days. The claudication distance was less than 50 m. The left-sided symptoms were predominant. Neurologic examination revealed the weakness of the ankle dorsiflexors (grade 3/5 on the right side, grade 0/5 on the left side) and extensors of the great toe (grade 3/5 on the right side, grade 0/5 on the left side) and plantar flexors of the ankle (grade 4/5 on both sides). X-rays and MRI of the patient revealed a grade 1 spondylolisthesis at L5–S1 with severe lumbar canal stenosis at the L4–L5

and L5–S1 levels (Figure 1). There was a cystic lesion within the ligamentum flavum at the L4–L5 level in the midline and slightly to the left. We performed posterior instrumentation at the L4–S1 level, transforaminal lumbar interbody fusion at the L5–S1 level, and lamino-foraminotomy with cyst excision at the L4–L5 level (Figure 2). There were dense adhesions between the ligamentum flavum and the thecal sac that were released, and the cyst was removed. Histopathological examination of excised specimen was consistent with a ligamentum flavum cyst (Figure 2). Postoperatively, there was a significant improvement in pain symptoms. The weakness also improved completely, and she was asymptomatic at 1 year follow-up.

Figure 2. Case 1. (a, b) Postoperative anteroposterior and lateral x-rays of the patient showing posterior instrumentation from L4 to S1 and transforaminal lumbar interbody fusion at the L5–S1 level. (c) Image showing the excised ligamentum flavum cyst measuring about 1 cm in length. (d) Histopathological slide of the cyst shows a cystic lesion lined by a fibro-connective tissue with mild chronic inflammatory infiltrate and fibroblast proliferation. Few proliferating blood vessels are seen. There is no lining epithelium, consistent with a ligamentum flavum cyst.

Case 2

A 69-year-old male presented to our emergency department with an acute onset progressive weakness of both legs for the past week. He had a history of low back pain with neurogenic claudication in both legs for 5 years. The patient had a claudication distance of fewer than a hundred meters. He had a history of trivial fall at home 1 month previously.

Clinical examination revealed the weakness of bilateral extensors of the great toe (1/5 on the right side, 3/5 on the left side) and right ankle plantar flexors (3/5 on the right side). X-rays of the lumbosacral spine suggested degenerative changes, and MRI of the patient suggested canal stenosis at the L4–L5 level with grade 1 spondylolisthesis at the L4–L5 level. We missed the ligamentum flavum cyst on MRI (Figure 3). We performed a posterior

decompression by laminectomy of L4 along with posterolateral fusion from L4 to S1 (Figure 4). We found a cystic lesion in the midline compressing the thecal sac (Figure 4). Retrospectively, on reviewing the MRI films, a ligamentum flavum cyst was noted in the midline at the L4–L5 level (Figure 3). Histopathological examination confirmed the diagnosis of ligamentum flavum cyst. He had good improvement in pain symptoms and foot weakness and returned to work at 6-month follow-up. He was doing well at 2-year follow-up.

Case 3

A 70-year-old male with a chronic history of back pain with bilateral buttock and leg pain for 3 years presented with aggravated symptoms for the past 1 month. Clinical examination revealed weakness of

Figure 3. Case 2. (a, b) Sagittal T1- and T2-weighted magnetic resonance images of the patient showing a lesion hyperintense on T2 and hypointense on T1 at the L4–L5 level within the posterior spinal canal compressing the thecal sac (marked with blue arrow). (c, d) Axial T1- and T2-weighted magnetic resonance images at the L4–L5 level of the patient showing a lesion with hypointense signal (similar to cerebrospinal fluid signal) on T1 and hyperintense on T2 in the midline (marked with blue arrow) compressing the thecal sac.

the ankle dorsiflexors (grade 1/5 on both sides), of the extensors of the great toe (grade 1/5 on both sides), and of the hip abductors (grade 2/5 on both sides).

MRI of the lumbar spine showed severe lumbar canal stenosis causing neural compression at the L3–L4 and L4–L5 levels. A 2-level posterior decompression by laminectomy from L3 to L5 was done, and a cystic mass within ligamentum flavum was noted on the left side. The cyst was completely excised, and histopathological examination of the excised specimen was consistent with a ligamentum flavum cyst. The weakness improved gradually, and the patient was able to walk unsupported at 6-

month follow-up. He was doing well at 2-year follow-up.

DISCUSSION

We performed a PUBMED and EMBASE database search using the MeSH (Medical Subject Headings) terms “ligamentum flavum” and “cysts” for articles published to April 2019. All articles in the English-language literature describing ligamentum flavum cysts were included regardless of study design. All relevant and related articles were studied. Full-text articles were retrieved, and the neurological status of all the patients in the

Figure 4. Case 2. (a, b) Postoperative anteroposterior and lateral x-rays of the patient showing posterior instrumentation from L4 to S1 with accurately placed screws. (c) Specimen showing the excised laminae (marked with white arrow) along with ligamentum flavum (marked with yellow arrow) en masse. The ligamentum flavum cyst (marked with blue arrow) can be clearly seen on the inner surface of the ligamentum flavum. (d) Histopathological slide of the cyst showing fibro-elastic tissue with chondroid metaplasia and areas of calcification. There is no lining epithelium, consistent with a ligamentum flavum cyst.

literature with ligamentum flavum cysts was noted wherever available.

We could identify 26 articles on ligamentum flavum cysts in the lumbar spine after excluding irrelevant articles. Seventy-seven cases of ligamentum flavum cysts in the lumbar spine have been reported to date (Table). Seven studies describing 20 cases of lumbar ligamentum flavum cysts have been reported to have a motor weakness (Table). However, only 1 case among them has been reported to have an acute onset of motor weakness. Our series included 3 patients with acute onset motor weakness and biopsy-proven ligamentum flavum cysts. All the patients had good improvement in neurological status after surgical decompression and cyst excision.

Juxtafacetal cyst is a common term used in the literature for any cyst arising from the posterior elements of the spinal canal.^{1,2} However, identifying the origin of the cyst and differentiating different types of cysts can help in individualizing the management strategies. Whereas a synovial cyst has communication with the facet joint and is lined by a synovial lining, ganglion cysts are pseudocysts lined by a fibrous wall.^{2,4} A ligamentum flavum cyst is an entity less described in the literature. Flavum cysts are unique in having no communication with the facet joint, arising within the ligamentum flavum, and having no epithelial lining.^{19,22,30} They can grow into the spinal canal and compress the neural structures and produce symptoms of neurogenic claudication or radiculopathy or neurologic deficit.^{13,17,19,20,22,23,30–32}

Table. Chronological list (from the most recent to the earliest) of relevant studies on ligamentum flavum cysts in the lumbar spine to April 2019. The studies that reported motor deficits due to ligamentum flavum cysts are in bold.

Segmental instability has been described as a major role in the pathogenesis of ligamentum flavum cysts.^{23,34,35} The hypermobility at the lower lumbar segments associated with repeated micro-trauma due to instability results in the weakening of elastic fibers within the flavum that consequently undergo cystic degeneration. We found a segmental instability with grade 1 spondylolisthesis in 1 of the 3 cases at the same level and in 1 case at the adjacent level. We are of the opinion that the instability may contribute to the formation of ligamentum flavum cysts. Hence, stabilization of the segment becomes equally important to cyst resection and decompression to prevent a recurrence in those cases that are associated with instability. The occurrence in elderly patients with degenerative changes in the spine suggests that the aging process may have also contributed to the formation of ligamentum flavum cysts.

Wildi et al²³ reported that the ligamentum flavum cysts exclusively occurred in the medial part of the ligamentum flavum and caused thickening of the ligament. However, DiMaio et al²² reported that most of the cysts were located laterally within the spinal canal due to the thin ligament and less resistance at the posterior recesses laterally. We

found that the cysts were located in the medial part of flavum in 2 of our cases and laterally in 1 case.

Seo et al¹⁴ reported that a majority of the patients with ligamentum flavum cysts present with radicular pain (97% of the cases) or neurologic symptoms and may mimic symptoms of intervertebral disc herniation. However, the acute onset of neurologic deficits has been very rarely documented. Rupture of vessels within the cyst with subsequent hemorrhage and neural compression has been proposed by Gazzeri et al²⁰ as the reason for acute onset of motor weakness in their case. They could appreciate a subacute hematoma on MRI imaging done 2 days after the onset of symptoms. However, chronic hematoma into the cyst has been noted in other studies as well.^{27,36,37} In our series, all the cases presented late after an acute onset of neurologic deficit, and MRI did not reveal a hematoma. We assume that the late presentation may have led to the negative finding on MRI in our study.

The thickened ligamentum flavum containing the cyst has variable signals on T1-weighted images and a high-intensity signal on T2-weighted images on MRI. Nizamani¹¹ mentioned that ligamentum flavum cysts may be difficult to diagnose on MRI, as the usual MRI images are focused on the intervertebral discs. They can be easily identified on MRI if looked at carefully. However, the presence of blood, gas, air, or proteinaceous content can alter the signal intensity.³⁸ In our study, all 3 cases had a hyperintense signal on T2-weighted MRI imaging and a hypointense signal on T1-weighted MRI imaging.

There are no high-quality studies on the management of lumbar juxta facet cysts.⁶ However, differentiating synovial cysts from ligamentum flavum cysts is important, as synovial cysts often adhere to dura, difficult to resect, and commonly require facet joint exploration.¹¹ Percutaneous aspiration of the cysts has been associated with a high recurrence and failure. Spontaneous regression of cysts has also been documented in synovial cysts. The management of symptomatic ganglion cysts is usually surgical, although spontaneous regression has been documented similar to synovial cysts. Conservative management has not been successful, and percutaneous steroid injections or aspiration of cysts have not shown good long-term results in the management of ligamentum flavum cysts.¹⁴ In view of severe symptoms and acute onset of neurologic deficit, surgical treatment was advised in all our

cases. All 3 patients responded well to surgical decompression with cyst excision and had good improvement in the neurological status postoperatively. Dural adhesions may cause difficulty in the removal of cysts en masse and cause surgical morbidity. In our study, we found dural adhesions and difficulty removing the cyst in 1 case. However, there were no complications, and the cyst could be removed completely.

Our study suggests that ligamentum flavum cysts have the potential to cause acute neurological deficits and respond well to surgery. However, due to the rarity of occurrence of the entity and no high-quality evidence, the role of conservative treatment in patients who present with ligamentum flavum cysts cannot be commented on.

CONCLUSIONS

Ligamentum flavum cysts should remain in the differential diagnosis of a patient who presents with symptoms of lumbar canal stenosis, especially those with an acute onset of neurologic deficit. Careful preoperative reading of the MRI images may aid in the diagnosis. Such patients have good outcomes with surgery.
